Multimedia Streaming in Home/Office

- Real-time multimedia flows in home/office networks
 - High bandwidth
 - QoS requirements
- No messy wires

Supporting Wireless Media Sessions

- Desired properties
 - **Continuous access** to radio spectrum, high-bandwidth transmissions
 - Support multiple **concurrent** flows
 - **Adapt** to time-varying traffic demands

Can We Use WiFi?

- The 2.4G/5G ISM band is too crowded → **no dedicated access** 😞

- Per-packet CSMA contention → **frequent & unpredictable disruptions** 😞

Per-session Frequency Domain Sharing

- Simultaneous media sessions work in **parallel** on **isolated** frequencies

No interference

Continuous spectrum access in time

On-demand frequency usage

Is This Feasible?

- **Opportunity for new dedicated frequency band**
 - FCC has auctioned & released new spectrum
 - Start from a **clean** spectrum band
- **Opportunity to deploy new access mechanism**
 - The new National Broadband Plan encourages new dynamic spectrum access mechanisms

Our Design: **Jello, per-session frequency domain sharing**

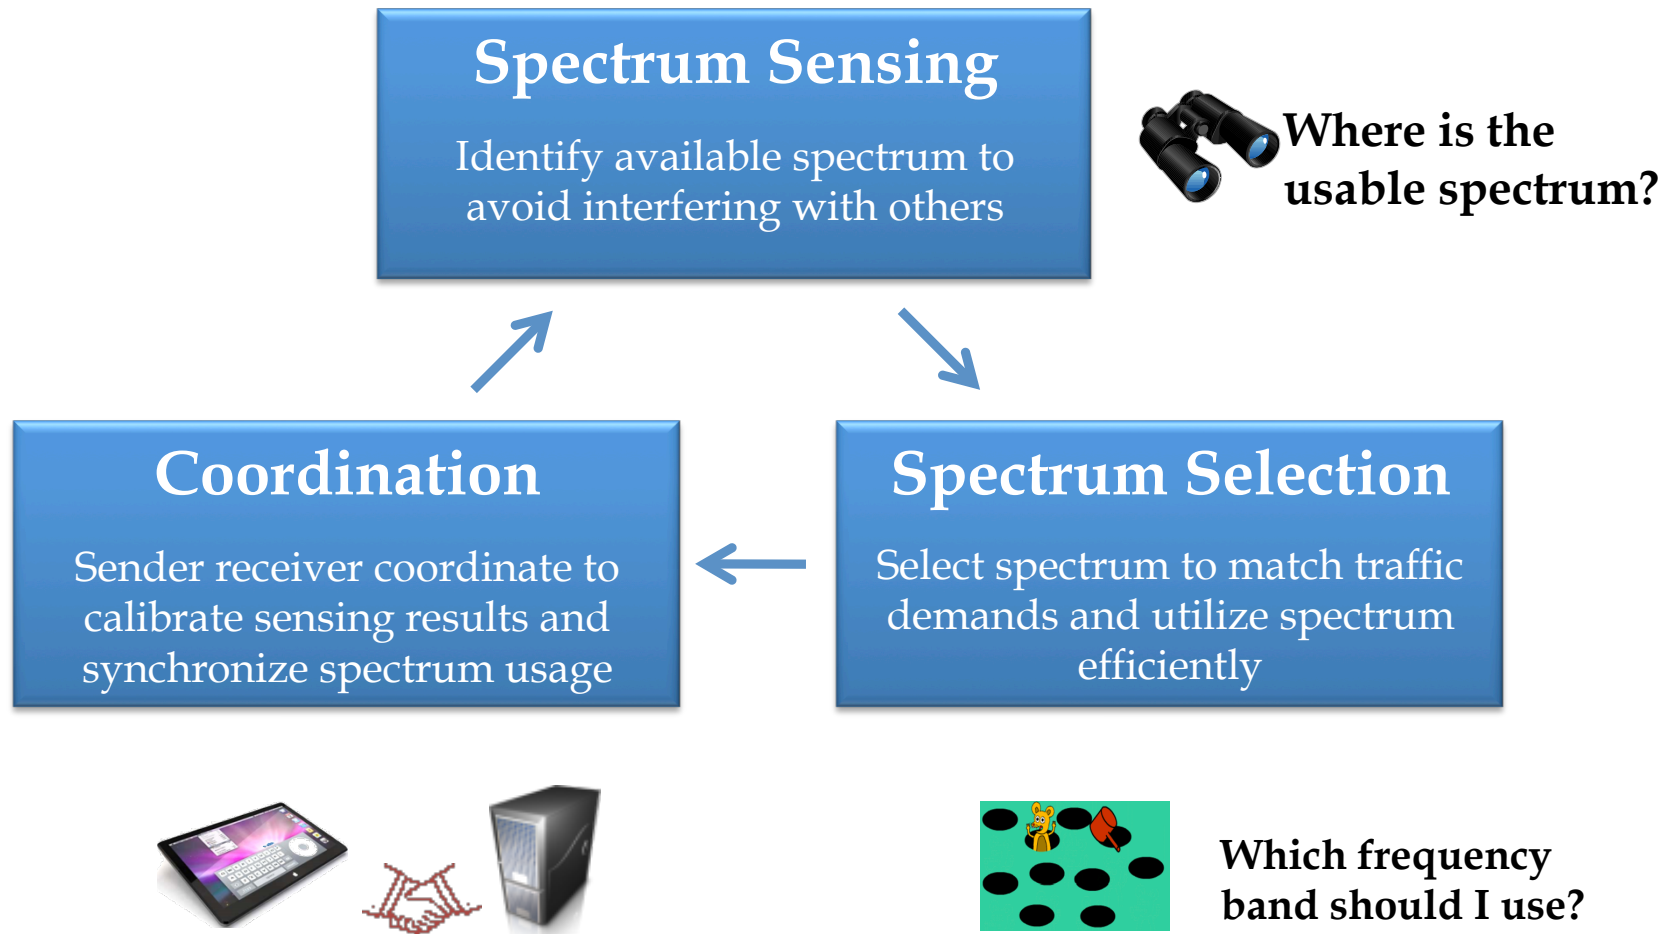

Jello: Decentralized Home Media System

- **Decentralized** system → wireless home
 - Flexible
 - Support different types of device
 - Self-configuring, self repairing
 - Low cost
 - No extra control radio
 - No central controller
- Utilizing **frequency-agile** radios
 - Flexible, reprogrammable

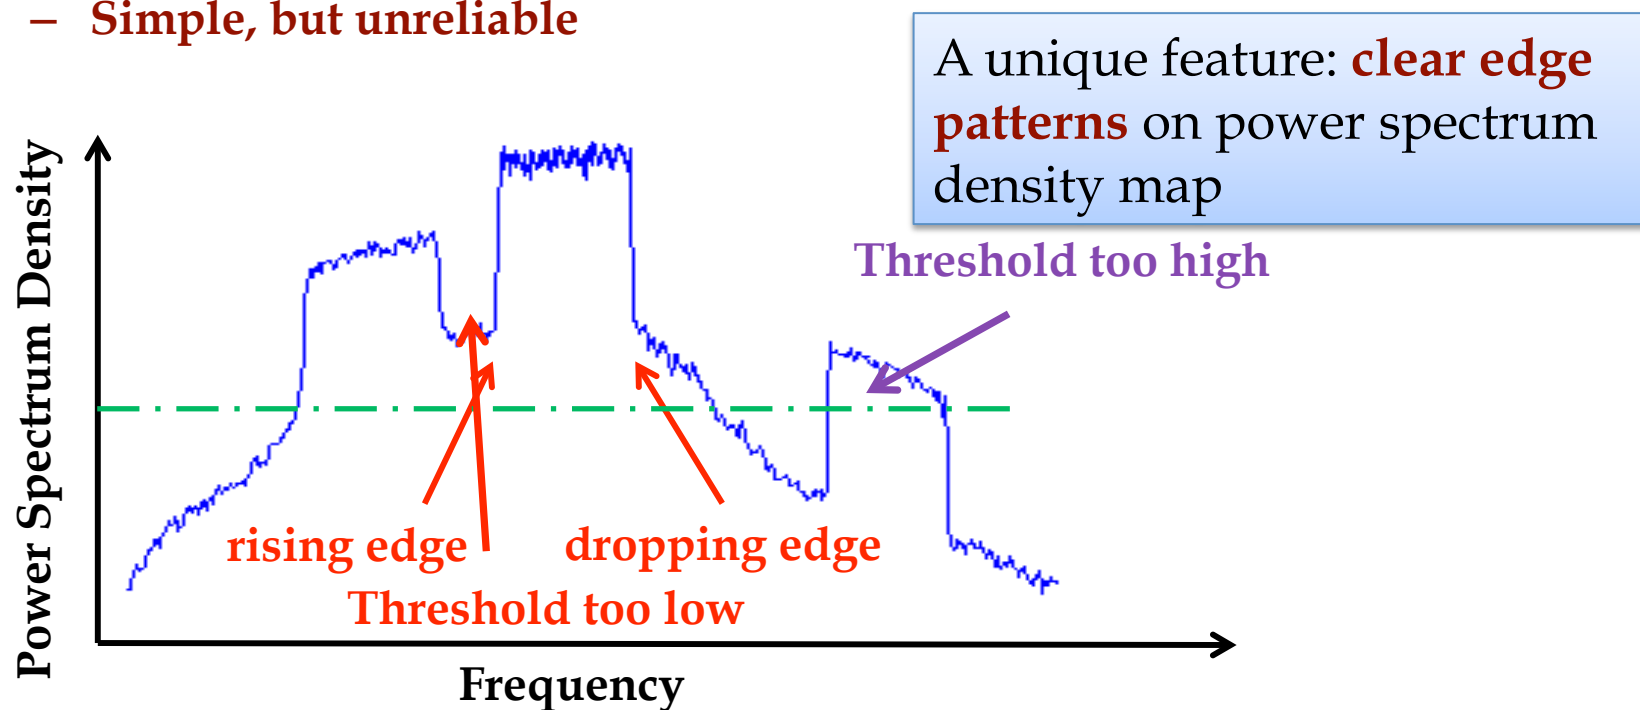

Jello's Key Components

How to Identify Free Spectrum?

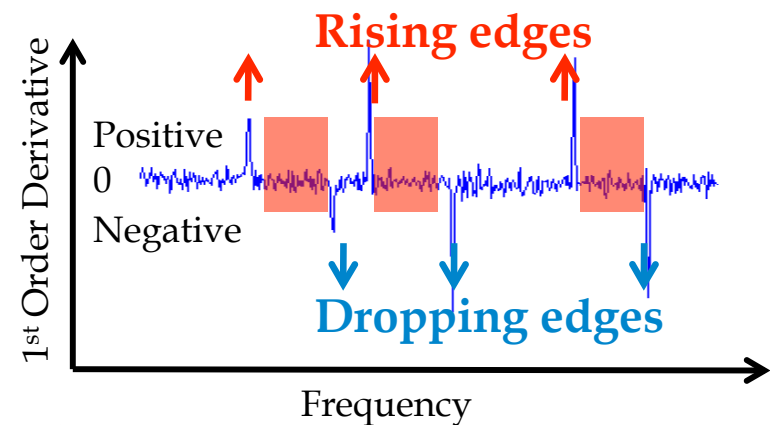

- Conventional sensing: energy detection
 - **Simple, but unreliable**

Jello devices identify and use such **edge patterns** to get better sensing!

Sensing via Edge Detection

- **Step 1: Preprocessing**
 - Smoothing by averaging over multiple observations
- **Step 2: Detecting edges**
 - Calculate 1st order derivative of the power spectrum map
 - Identify rising/dropping edges

😊 **Much more robust than energy detection!**

Choosing Frequency Blocks

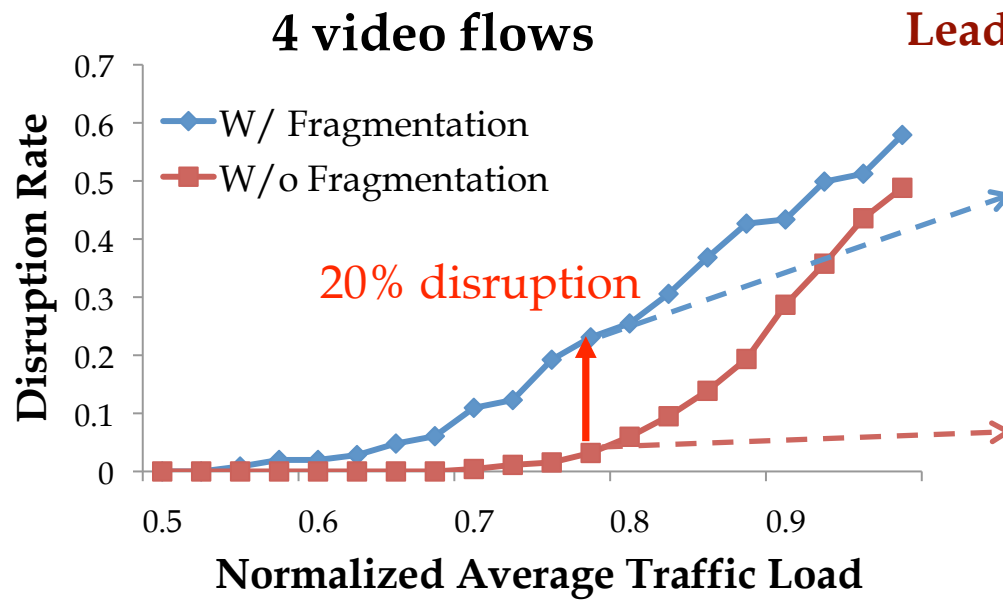

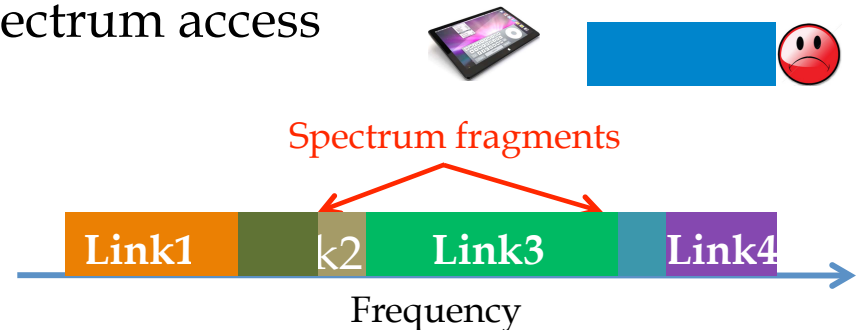

- Online resource allocation problem
 - First-fit, best-fit, worst-fit
- Jello uses **Best-Fit**
 - Selects the smallest available frequency block that can accept the current spectrum request

Our experiments reveal another fundamental challenge ...

Spectrum Fragmentation

- Like disks and memory, dynamic spectrum access creates **spectrum fragmentation**
 - Link comes and leaves
 - Link changes spectrum usage

Lead to significant media disruptions!

W/ Fragmentation

W/o Fragmentation

Solution 1: Defragmentation

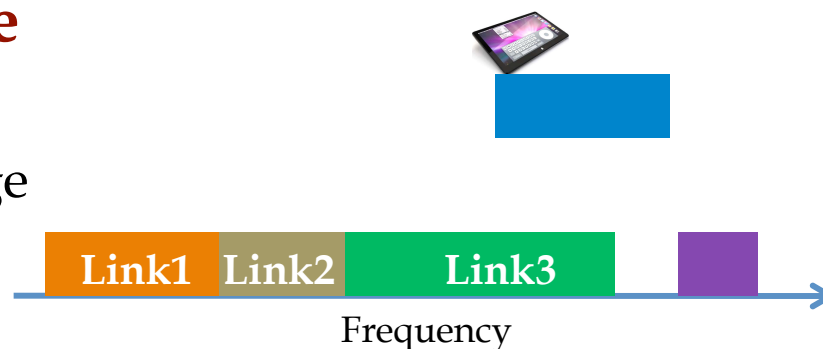

- Rearrange global spectrum usage

☹️ No, cannot stop all transmissions

- Our solution: **individual online defragmentation**

– Voluntarily change spectrum usage to reduce fragmentation

😊 Stays transparent to other links

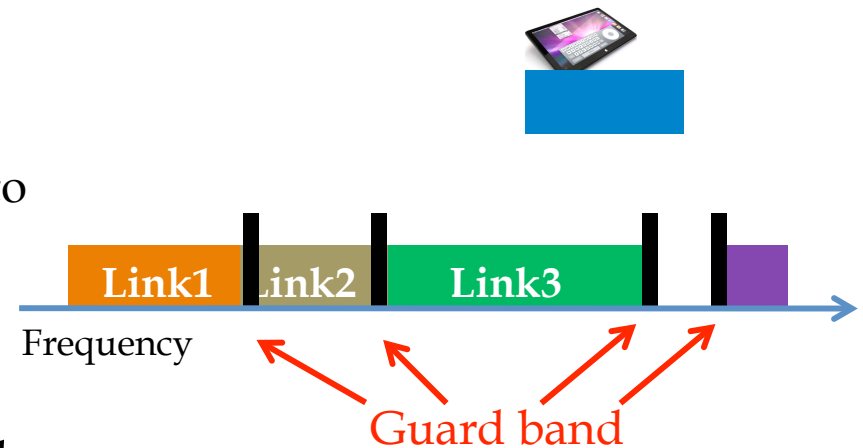

☹️ Self-disruption → Defrag occurs infrequently

Cannot eliminate fragmentation entirely, low levels of fragmentation may still exist

Solution 2: Non-Contiguous Spectrum Access

- Frequency-agile radios → redesign PHY to support non-contiguous spectrum access
 - Combine multiple spectrum slices to form a single transmission
 - Decentralized OFDMA
- 😊 Fragmentation is no longer harmful
- ☹️ Additional costs
 - Increased frequency overhead

Non-contiguous frequency access reduces the impact of fragmentation, but at additional costs

A Unified Solution in Jello

The two techniques are complementary to each other

Online defragmentation

😊 Remove most fragments

😞 Cannot completely remove fragmentation

Non-contiguous access

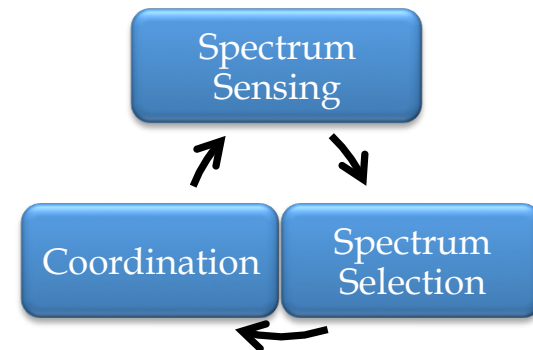

😊 Effective for low fragmentation

😞 Increased frequency overhead and hardware complexity

Proof of Concept Implementation

- GNU Radio
 - Software Define Radio
 - USRP frontend at 2.4G
 - Widely available, inexpensive, flexible
- Hardware limitations
 - Limited bandwidth: 500kHz OFDMA
 - Large and unpredictable proc. delay

See the paper for detailed implementation

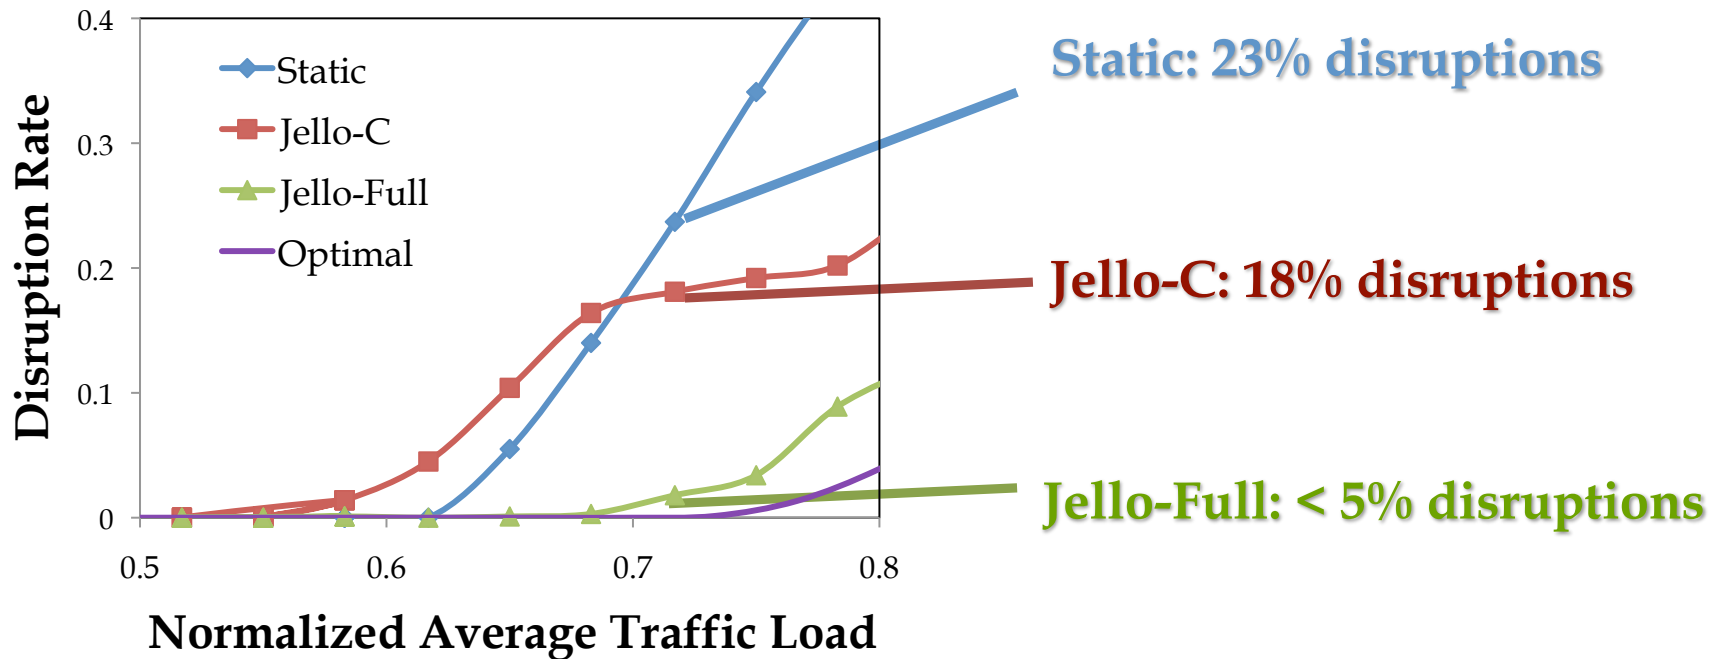

Testbed Evaluation

- 8-node GNU Radio testbed
 - 4 concurrent flows
 - 12m x 7m room with various furniture and walls
- Traffic load
 - Video and synthetic traces
- Evaluated 4 systems
 - **Static**: Partition spectrum equally, WiFi-like
 - **Jello-C**: Jello with contiguous frequency access
 - **Jello-Full**: Full version of Jello
 - **Optimal**: Oracle solution w/o fragmentation and overhead

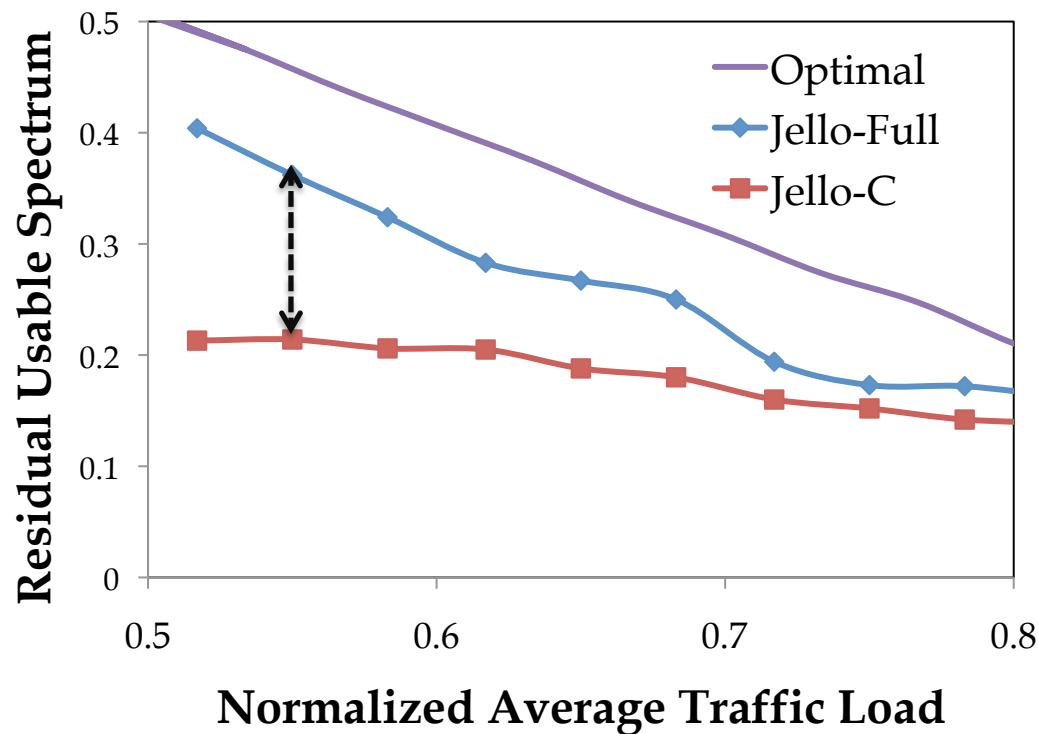

Overall Media Quality

Video Disruption Rate: percentage of time video is disrupted

Spectrum Usage Efficiency

Residual Usable Spectrum: the amount of spectrum a new link can use

45% more spectrum for a new session

Conclusions

- Jello: the 1st system supporting demanding wireless media sessions
 - **Per-session frequency domain sharing**
 - Detect available spectrum: **Edge-detection spectrum sensing**
 - Reduce spectrum fragmentation: **Non-contiguous spectrum access + online defragmentation**
- We deploy Jello on 8-node GNU Radio testbed
 - Support 4 concurrent flows
 - Provide high utilization and adapt to dynamic demands

Papyrus

Proliferation and innovation of wireless technologies require significant amounts of radio spectrum. Recent government policy reforms by the FCC are paving the way by freeing up spectrum for a new generation of frequency-agile wireless devices based on software defined radios (SDRs). Despite recent advances in experimental SDR platforms, further research into SDR MAC protocols or applications requires an experimental platform for managing physical spectrum access.

We have developed Papyrus, a software platform for wireless researchers to develop and experiment dynamic spectrum systems using currently available SDR hardware. Papyrus manages the complexities of spectrum access at the physical layer, exporting a clean, manageable abstraction to the MAC layer. Papyrus provides [two fundamental building blocks](#) at the physical layer: flexible non-contiguous frequency access and robust usable frequency detection. Researchers can deploy and experiment new MAC protocols and applications on Papyrus, which is available on the USRP GNU Radios, but can be adapted to run on all current SDR platforms. We demonstrated the use of Papyrus as an experimental platform using [Jello](#), a distributed MAC overlay for high-bandwidth media streaming applications.

You can download the USRP GNU Radio implementation of Papyrus and Jello [here](#).

The following figure shows our demo at Infocom 2010. It includes 3 pairs of USRP GNU radio links, demonstrating fully decentralized spectrum sharing. We also use 1 USRP as the spectrum analyzer. Click [here](#) to watch our Demo video.
