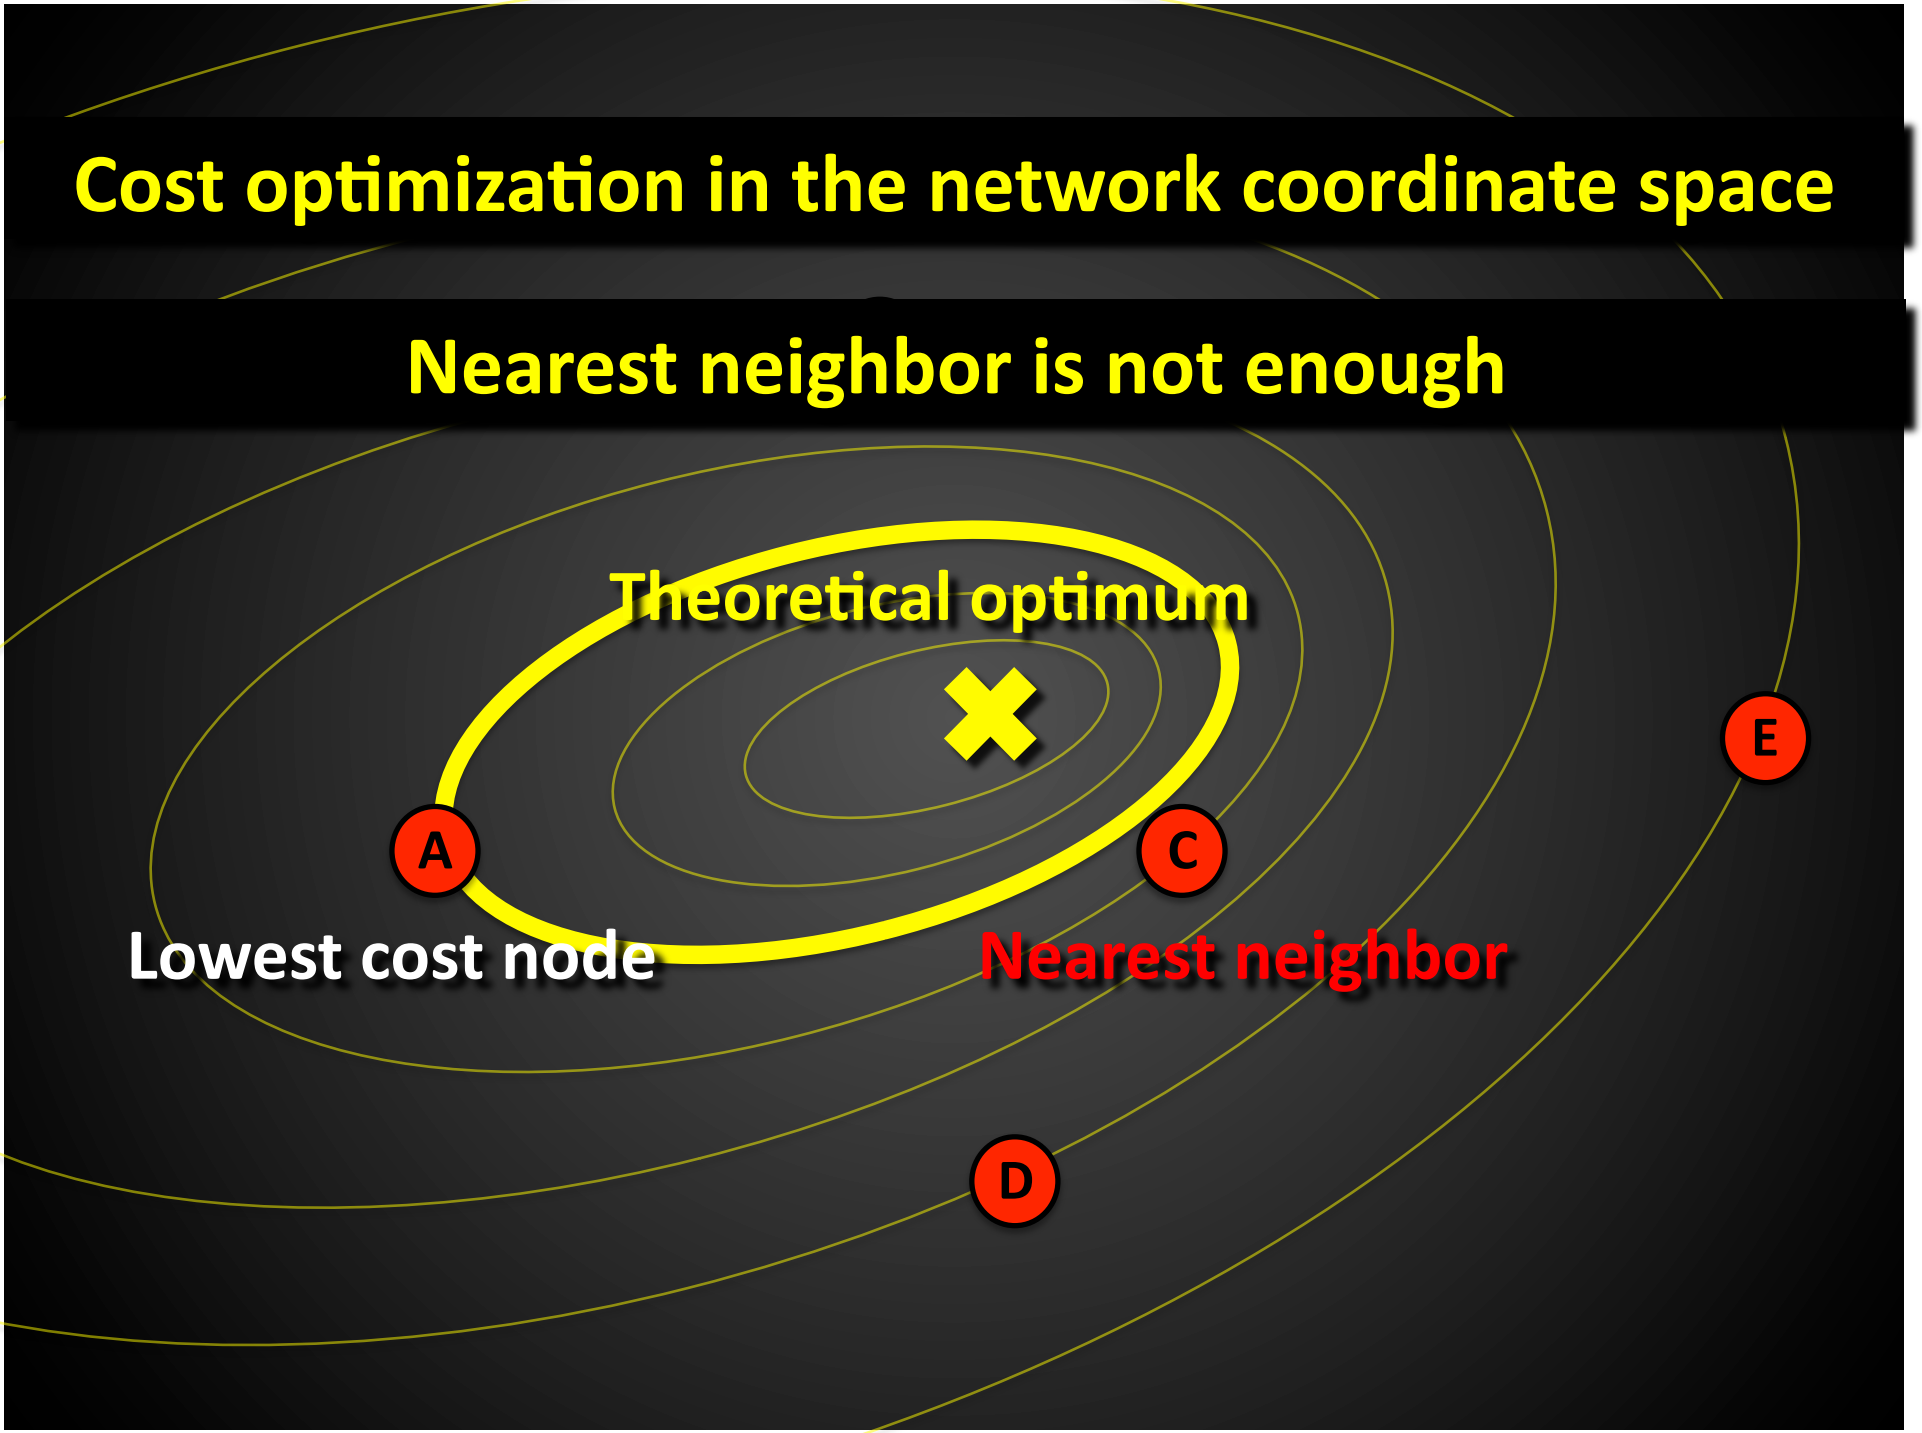
Cost optimization in the network coordinate space

Nearest neighbor is not enough



Sherpa

- Overlay network system that finds the lowest cost node under latency constraints
- Broad classes of latency-based cost functions, without knowing all the nodes that we are querying

1. Network coordinates
2. Voronoi regions

} Overlay setup

3. Compass routing
4. Gradient descent

} Querying/Node discovery

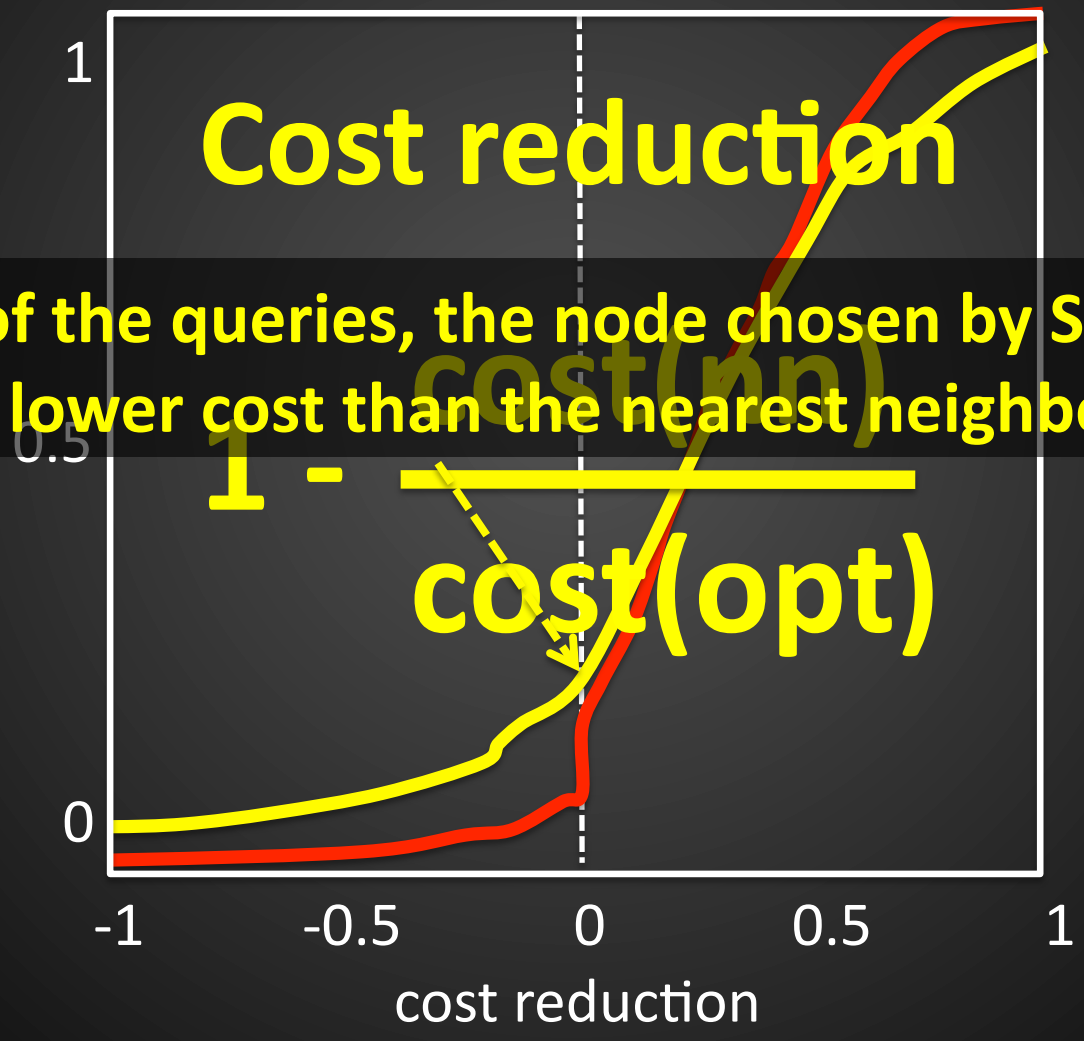
Evaluation

- Two latency data sets:
  - 1715 DNS servers, 213 PlanetLab nodes
  - network coordinate system: Vivaldi
- 1,000 queries: “find centroid of 30 nodes”

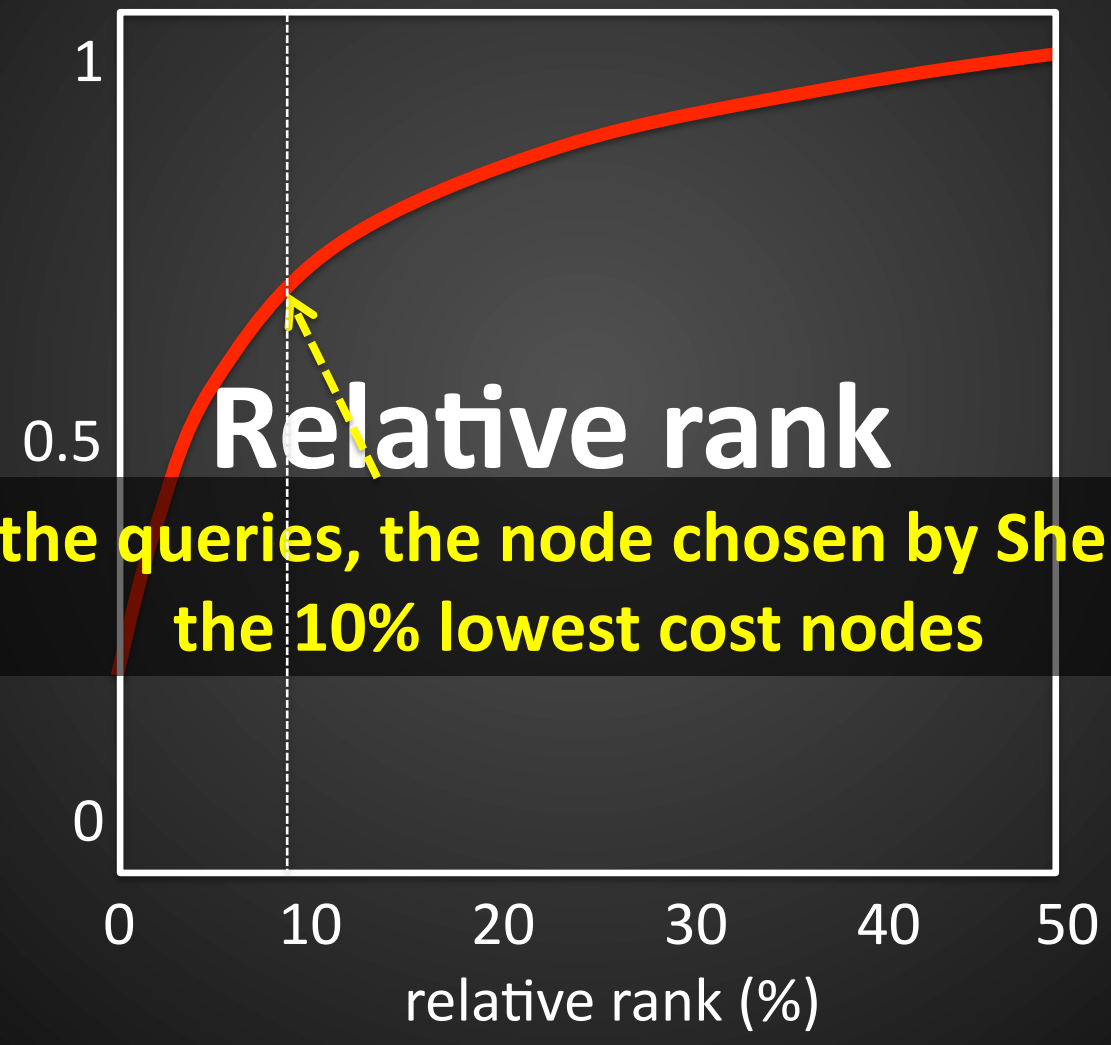
$$\text{cost}(m) = \frac{\sum_{i=1}^{N} d(m, p_i)}{N} + \\ +(\max_i(d(m, p_i)) - \min_i(d(m, p_i)))^2$$

Nearest neighbor is not enough



For 80% of the queries, the node chosen by Sherpa has a lower cost than the nearest neighbor

Relative ranking



For 65% of the queries, the node chosen by Sherpa is among the 10% lowest cost nodes

Conclusions and Future Work

- Generalized node selection with network coordinates
- Sherpa finds the lowest cost node

- Implementation
- Cost functions
- Other applications: split TCP, route avoidance
